Outline

- Approximation of multivariate functions
- Structural assumptions: active variables, SPAM's, ...
- Ridge functions single neurons:
 - Recovery algorithms
 - Lower bounds
- Sums of ridge functions one layer neural networks:
 - Non-linear optimization
 - Whitening
 - . . .

Classical task of approximation/sampling:

Given a function f with some properties (i.e. from some set) and few its function values $y_1 = f(x_1), \ldots, y_n = f(x_n)$ generate a function g, which is close to f in some sense.

Typically, the error (i.e. the distance of f and g) decays with n. Well known for many classical function spaces, like Sobolev spaces, Besov spaces, Triebel-Lizorkin spaces, etc.

Typical decay: $n^{-s/d}$

Neurons and neural networks

Sums of ridge functions

Curse of dimension

Many classical problems suffer from exponential dependence of the results on d!

Example: Approximation of smooth functions Let $\mathcal{F}_d := \{f : [0,1]^d \to \mathbb{R}, \|D^{\alpha}f\|_{\infty} \le 1, \alpha \in \mathbb{N}_0^d\}$ **Smoothness does not help!...?!** Infinitely differentiable functions on $\Omega = [0,1]^d$:

Novak, Woźniakowski (2009): Initial error is the same as error of uniform approximation for $n \le 2^{\lfloor d/2 \rfloor} - 1$... curse of dimension!

... the number of sampling points must grow exponentially in d

Structural assumptions

• Active variables:

R. DeVore, G. Petrova, and P. Wojtaszczyk: Approximation of functions of few variables in high dimensions, Constr. Appr. 2011:

$$f(x_1,\ldots,x_d):=g(x_{i_1},\ldots,x_{i_\ell}), \quad \ell\ll N.$$

1-Lipschitz function f can be recovered uniformly with accuracy ε from $C(\ell)\varepsilon^{-\ell}\log_2 d$ sampling points.

Use of low-rank matrix recovery:

H. Tyagi, V. Cevher, Learning non-parametric basis independent models from point queries via low-rank methods, ACHA 2014

Revisited also in

K. Schnass, J.V., Compressed learning of high-dimensional sparse functions, Proceedings of ICASSP '11

Sums of ridge functions

Structural assumptions

• **Sparse additive models:** H. Tyagi and J. Vybiral: Learning non-smooth sparse additive models from point queries in high dimensions, Constr. Appr. 2019:

 $r_0 = 1, \ f: [-1,1]^d \rightarrow \mathbb{R}$

$$f(\mathbf{x}) = \sum_{j \in \mathcal{S}_1} \phi_j(\mathbf{x}_j),$$

where $x = (x_1, \dots, x_d)$ and $\mathcal{S}_1 \subset \{1, \dots, d\}$ with $|\mathcal{S}_1| \ll d$

$$\begin{split} r_{0} &= 2, \ f: [-1,1]^{d} \to \mathbb{R} \\ f(x) &= \sum_{j \in \mathcal{S}_{1}} \phi_{j}(x_{j}) + \sum_{(j_{1},j_{2}) \in \mathcal{S}_{2}} \phi_{(j_{1},j_{2})}(x_{j_{1}},x_{j_{2}}), \\ \text{with } \mathcal{S}_{2} \subset {\binom{\{1,\ldots,d\}}{2}} \text{ and } |\mathcal{S}_{2}| \ll {\binom{d}{2}} \end{split}$$

Ridge functions

Ridge functions

Let $g : \mathbb{R} \to \mathbb{R}$ and $a \in \mathbb{R}^d \setminus \{0\}$. Ridge function with ridge profile g and ridge vector a is the function

 $f(x) := g(\langle a, x \rangle).$

Constant along the hyperplane $a^{\perp} = \{y \in \mathbb{R}^d : \langle y, a \rangle = 0\}$ and its translates.

More general, if $g : \mathbb{R}^k \to \mathbb{R}$ and $A \in \mathbb{R}^{k \times d}$ with $k \ll d$ then

$$f(x) := g(Ax)$$

is a k-ridge function.

Ridge functions in approximation theory

Approximation of a function by functions from the dictionary

$$D_{ ext{ridge}} = \{ arrho(\langle k, x
angle - b) : k \in \mathbb{R}^d, b \in \mathbb{R} \}$$

- Fundamentality
- Greedy algorithms

Ridge functions

Ridge functions: Approximation algorithms

k = 1: $f(x) = g(\langle a, x \rangle)$, $||a||_2 = 1$, g smooth

Approximation has two parts: approximation of g and of a

Recovery of *a* - from $\nabla f(x)$:

$$abla f(x) = g'(\langle a, x \rangle)a,
abla f(0) = g'(0)a.$$

After recovering a, the problem becomes essentially one-dimensional and one can use arbitrary sampling method to approximate g.

 $g'(0) \neq 0 \dots g'(0) = 1$

Ridge functions

Neurons and neural networks

Sums of ridge functions

A.Cohen, I.Daubechies, R.DeVore, G.Kerkyacharian, D.Picard, '12 *Capturing ridge functions in high dimensions from point queries*

- $k = 1 : f(x) = g(\langle a, x \rangle)$
- $f:[0,1]^d \to \mathbb{R}$
- $g \in C^{s}([0,1]), \ 1 < s$
- $\|g\|_{C^s} \leq M_0$
- $\|a\|_{\ell^d_q} \le M_1, 0 < q \le 1$
- *a* ≥ 0

Then

$$\|f - \hat{f}\|_{\infty} \leq CM_0 \left\{ L^{-s} + M_1 \left(\frac{1 + \log(d/L)}{L} \right)^{1/q-1} \right\}$$

using 3L + 2 sampling points

Sums of ridge functions

• First sampling along the diagonal

$$\frac{i}{L} \mathbf{1} = \frac{i}{L} (1, \dots, 1), i = 0, \dots, L :$$

$$f\left(\frac{i}{L}\mathbf{1}\right) = g\left(\left\langle\frac{i}{L}\mathbf{1}, a\right\rangle\right) = g(i||a||_1/L)$$

- Recovery of g on a grid of $[0, ||a||_1]$
- Finding i_0 with largest $g((i_0+1)||a||_1/L) g(i_0||a||_1/L)$
- Approximating D_{φj} f(i₀/L · 1) = g'(i₀||a||₁/L)⟨a, φ_j⟩ by first order differences
- Then recovery of a from ⟨a, φ₁⟩,..., ⟨a, φ_m⟩ by methods of compressed sensing (CS)

Ridge function

Sums of ridge functions

Artificial Neuron

 \ldots gets activated if a linear combination of its inputs grows over a certain threshold \ldots

- Inputs $x = (x_1, \ldots, x_n) \in \mathbb{R}^n$
- Weights $w = (w_1, \dots, w_n) \in \mathbb{R}^n$
- Comparing $\langle w, x
 angle$ with a threshold $b \in \mathbb{R}$
- Plugging the result into the "activation function" jump (or smoothed jump) function σ

Artificial neuron is a function

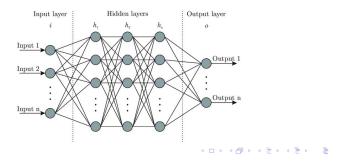

$$\mathbf{x} \to \sigma(\langle \mathbf{x}, \mathbf{w} \rangle - \mathbf{b}),$$

where $\sigma : \mathbb{R} \to \mathbb{R}$ might be $\sigma(x) = \operatorname{sign}(x)$ or $\sigma(x) = e^x/(1 + e^x)$, etc.

Artificial neural networks

Artificial neural network is a directed, acyclic graph of artificial neurons

- Input: $x = (x_1, \ldots, x_n) \in \mathbb{R}^n$
- First layer of neurons: $y_1 = \sigma(\langle x, w_1^1 \rangle - b_1^1), \dots, y_{n_1} = \sigma(\langle x, w_{n_1}^1 \rangle - b_{n_1}^1)$
- The outputs y = (y₁,..., y_{n₁}) become inputs for the next layer ...; last layer outputs y ∈ ℝ

ction Ridge functions Neurons and neural networks	Sums of ridge functions
---	-------------------------

M. Fornasier, J.V., I. Daubechies, Robust and resource efficient identification of shallow neural networks by fewest samples to appear in IMA: Information and Inference

Recovery of

$$f(x) = \sum_{j=1}^{m} g_j(\langle a_j, x \rangle)$$

- one layer of a neural network
 - Special case of f(x) = g(Ax), but we would like to have m onedimensional problems, and not one m-dimensional
 - We would like to identify a_1, \ldots, a_m , then g_1, \ldots, g_m

Ridge function: 000000 Neurons and neural networks $_{\rm OOO}$

Sums of ridge functions

• Step 1.: Sampling of

$$abla f(x) = \sum_{j=1}^m g_j'(\langle a_j, x \rangle) a_j$$

at different points gives elements of

$$A = \operatorname{span}\{a_1, \ldots, a_m\} \subset \mathbb{R}^d$$

- We sample (only) differences and obtain an approximation $\tilde{A} \sim A$, upper bound on $\|P_A P_{\tilde{A}}\|_F$
- \overline{A} matrix, columns are a basis of \widetilde{A}
- We consider

$$\tilde{f}(y) = \sum_{i=1}^{m} g_i(\langle \bar{A}^T a_i, y \rangle) = \sum_{i=1}^{m} g_i(\langle a_i, \bar{A}y \rangle)$$

<ロト<部ト<差ト<差ト 差 のQで 17/23

troduction 2000	Ridge functions 000000	Sums of ridge functions

Recovery of individual
$$a_i$$
's for $d = m$?

• Step 2.: Second order derivatives:

$$abla^2 f(x) = \sum_{j=1}^m g_j''(\langle a_j, x \rangle) a_j \otimes a_j$$

Put

$$\mathcal{A} = \operatorname{span}\{a_i \otimes a_i : i = 1, \dots, m\} \subset \mathbb{R}^{m \times m}$$

- We can recover $\tilde{\mathcal{A}}\sim \mathcal{A}$ - an approximation of \mathcal{A}

ion	Ridge functions	Neurons and neural networks	Sums of ridge functions
-----	-----------------	-----------------------------	-------------------------

- Step 3.: We try to find matrices in *A*, which are close to a_i ⊗ a_i ∈ A
- We look for matrices in $\tilde{\mathcal{A}}$ with the "smallest" rank
- We analyze the non-convex problem

(*) arg max
$$\|M\|$$
, s.t. $M \in \tilde{\mathcal{A}}, \|M\|_F \leq 1$

Every algorithm, which is able to find an approximation of a₁ ⊗ a₁ can also land close to a_j ⊗ a_j, j = 2,..., m, hence it must be non-convex

Analysis of (\star) :

- Let M be a local maximizer of (\star)
- Eigenvalues $\lambda_1, \ldots, \lambda_m$, eigenvectors u_1, \ldots, u_m

- Then

$$u_j^{\mathsf{T}} X u_j = \lambda_j \langle X, M
angle$$
 for every $X \in ilde{\mathcal{A}}$

and every j with $|\lambda_j| = \|M\|$

- If a_1, \ldots, a_m are nearly orthonormal, then $|\lambda_1| = \|M\|$ is unique and

$$2\sum_{k=2}^{m} \frac{(u_1^T X u_k)^2}{|\lambda_1 - \lambda_k|} \le \|M\| \cdot \|X - \langle X, M \rangle_F M\|_F^2 \quad \text{for all } X \in \tilde{\mathcal{A}}$$

second Hadamard variation formula

The Algorithm leads to \hat{a} with $\|\hat{a} - a_{j_0}\|_2$ small.

Ridge function

Neurons and neural networks

Sums of ridge functions

Whitening: If a_i 's are not orthonormal, we consider (any) positive definite

$$G = \sum_{i=1}^m \xi_i a_i \otimes a_i \in \mathcal{A}$$

and its singular value decomposition

$$G = UDU^T$$
,

then $W := D^{-1/2}U^T$ is the so-called *whitening matrix* and $\{\sqrt{\xi_i}Wa_i : i = 1, ..., m\}$ is an orthonormal basis.

Passive sampling: sampling points preselected at random from a distribution with known density

Identification of g_i's:

- $(\hat{a}_j)_{j=1}^m$ an approximation of $(a_j)_{j=1}^m$
- $(\hat{b}_j)_{j=1}^m$ the dual basis to $(\hat{a}_j)_{j=1}^m$
- $\hat{g}_j(t) := f(t\hat{b}_j).$

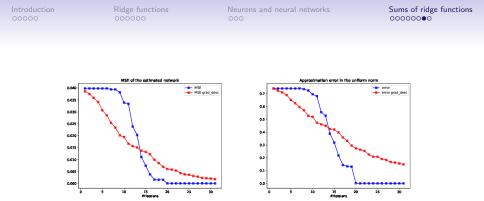

Figure: Average approximation error of 10 random networks with $m = 20, \varepsilon = 1$ in terms of MSE (left), uniform norm (right). The errors were measured over 10^5 datapoints generated uniform at random on the ball B_1^d .
